

AI Assisted Coding

Lab_Assignment_19.3

Goli Harini Reddy

Batch-08

2303A51544

Task 1 – Python to C++ Conversion Task:

Translate a simple Python class into C++ using AI assistance. Instructions:

- Prompt AI to convert a Python class representing a Student with attributes and methods into equivalent C++ code

- Ensure proper handling of:

o Constructors o

Data types o Access

specifiers

- Compile and run both versions to verify output consistency Expected Output:

An equivalent working C++ class translated from Python.

Task 1 – Python to C++ Conversion

Python Code

(parameter) name: Any

[2]
✓ 0s

```
class Student:
    def __init__(self, name, age, marks):
        self.name = name
        self.age = age
        self.marks = marks

    def display(self):
        print("Name:", self.name)
        print("Age:", self.age)
        print("Marks:", self.marks)

# Testing
s1 = Student("manu", 20, 85)
s1.display()
```

▼

```
... Name: manu
    Age: 20
    Marks: 85
```

Equivalent C++ Code

[9]
✓ 0s

```
%%writefile student.cpp
#include <iostream>
#include <string>

class Student {
private:
    std::string name;
    int age;
    int marks;

public:
    // Constructor
    Student(std::string n, int a, int m) {
        name = n;
        age = a;
        marks = m;
    }

    // Method to display student information
    void display() {
        std::cout << "Name: " << name << std::endl;
        std::cout << "Age: " << age << std::endl;
        std::cout << "Marks: " << marks << std::endl;
    }
};
```

```
[9] ✓ 0s  
};  
  
int main() {  
    // Create a Student object  
    Student s1("manu", 20, 85);  
  
    // Call the display method  
    s1.display();  
  
    return 0;  
}  
  
Writing student.cpp  
  
[10] ✓ 1s  
g++ student.cpp -o student_app  
  
[11] ✓ 0s  
!./student_app  
  
... Name: manu  
Age: 20  
Marks: 85
```

Observation:

- The overall logic of the class remained the same in both Python and C++.
- Python uses dynamic typing, whereas C++ requires explicit data type declaration.
- Constructors in C++ must be explicitly defined, unlike Python's `__init__` method.
- C++ requires access specifiers (public, private) to control data access.
- Python code is shorter and more readable, while C++ is more structured and strict.
- Compilation is required in C++, whereas Python runs directly without compilation.

Task 2 – Java to Python Function Conversion Task:

Convert a Java method that checks whether a number is prime into Python.

Instructions:

- Ask AI to translate a Java `isPrime()` method into Python
- Test the function with multiple inputs
- Ensure the Python version follows Pythonic syntax and logic Expected Output:

A correct Python function equivalent to the original Java prime- checking method.

```
[13] def is_prime(n):
✓ 0s   if n <= 1:
       return False
       for i in range(2, int(n**0.5) + 1):
           if n % i == 0:
               return False
       return True

       # Example usage:
       # print(is_prime(7))
       # print(is_prime(10))

Equivalent Python Code

[14] def is_prime(n):
✓ 0s   if n <= 1:
       return False
       for i in range(2, n // 2 + 1):
           if n % i == 0:
               return False
       return True

       # Testing
       print(is_prime(7))  # True
       print(is_prime(10)) # False

▼ True
  False
```

Observation:

- The core logic of checking prime numbers remained unchanged across both languages.
- Python code is simpler and shorter compared to Java.
- Java requires class and method structure, while Python allows standalone functions.
- Data types are explicitly defined in Java but not required in Python.
- Loop structure is more concise in Python using range().
- Python provides better readability and faster implementation.

Task 3 – Pseudocode to Python Implementation Task:

Translate a given pseudocode algorithm into Python using AI.

Instructions:

- Provide AI with pseudocode for sorting numbers (e.g., bubble sort or selection sort)
- Ask AI to convert it into executable Python code
- Validate correctness using sample input lists Expected Output:

A working Python program that correctly implements the pseudocode logic.

Task 3 – Pseudocode to Python

Pseudocode

START Input list FOR i from 0 to n-1 FOR j from 0 to n-i-1 IF arr[j] > arr[j+1] swap END

Python Code

```
16] def bubble_sort(arr):  
0s     n = len(arr)  
     for i in range(n):  
         for j in range(0, n - i - 1):  
             if arr[j] > arr[j + 1]:  
                 # Swap  
                 arr[j], arr[j + 1] = arr[j + 1], arr[j]  
     return arr  
  
# Testing  
data = [5, 2, 9, 1, 3]  
print("Sorted:", bubble_sort(data))  
... Sorted: [1, 2, 3, 5, 9]
```

Observation:

- Pseudocode helps in understanding the algorithm before coding.
- Translating pseudocode to Python is straightforward due to simple syntax.
- Python supports easy swapping of values using tuple unpacking.
- The logic of Bubble Sort remained the same after implementation.
- Testing with sample inputs confirmed correctness of the algorithm.
- Python reduces complexity in implementing algorithms compared to other languages.

Task 4 – SQL to Pandas Query Task:

Translate a SQL query into a Pandas DataFrame operation in Python.

Instructions:

- Provide AI with a SQL query (e.g., SELECT name, salary FROM employees WHERE salary > 50000).
- Ask AI to generate equivalent Pandas code.
- Test the generated code on a sample DataFrame.

Expected Output:

- Equivalent Pandas query that retrieves the correct subset of data.

Task 4 – SQL to Pandas

SQL Query

```
SELECT name, salary FROM employees WHERE salary > 50000;
```

Equivalent Pandas Code

```
[17] ✓ 0s ▶ import pandas as pd

# Sample Data
data = {
    'name': ['A', 'B', 'C', 'D'],
    'salary': [40000, 60000, 55000, 30000]
}

df = pd.DataFrame(data)

# Query
result = df[df['salary'] > 50000][['name', 'salary']]

print(result)
```

```
▼ ...   name  salary
1    B   60000
2    C   55000
```

Observation:

- SQL queries can be effectively translated into Pandas operations.
- SQL WHERE clause corresponds to filtering in Pandas.
- SQL SELECT is equivalent to column selection in Pandas.
- Pandas allows data manipulation directly within Python without a database.
- The output of both SQL and Pandas queries is consistent.
- Pandas is useful for data analysis and processing tasks in real-time applications.

Task 5 – Real-Time Application: Algorithm Translation Across

Languages Scenario:

A company maintains algorithms written in different programming languages.

Examples:

- Converting a Python searching algorithm into C
 - Translating a Java sorting program into JavaScript
- Instructions:
- Use AI to translate a selected algorithm between two programming languages
 - Execute and test both versions
 - Document translation challenges such as:

o Syntax differences o

Library support o

Memory management

Expected Output:

Equivalent, tested code implementations in two different programming languages.

Task 5 – Algorithm Translation (Python → C)

Python Linear Search

```
[18] ✓ Os
def linear_search(arr, key):
    for i in range(len(arr)):
        if arr[i] == key:
            return i
    return -1

print(linear_search([10, 20, 30], 20))
```

1

Equivalent C Code

```
[23] ✓ Os
%%writefile linear_search.c
#include <stdio.h>

int linearSearch(int arr[], int n, int key) {
    for(int i = 0; i < n; i++) {
        if(arr[i] == key)
            return i;
    }
    return -1;
}
```

```
[23] ✓ Os
int linearSearch(int arr[], int n, int key) {
    for(int i = 0; i < n; i++) {
        if(arr[i] == key)
            return i;
    }
    return -1;
}

int main() {
    int arr[] = {10, 20, 30};
    int result = linearSearch(arr, 3, 20);

    printf("Index: %d\n", result);
    return 0;
}
```

... Overwriting linear_search.c

```
[21] ✓ Os
!gcc linear_search.c -o linear_search_app
```

```
linear_search.c:19:1: error: expected identifier or '(' before '!' token
19 | !gcc linear_search.c -o linear_search_app
   | ^
```

```
[22] ✓ Os
!./linear_search_app
```

```
/bin/bash: line 1: ./linear_search_app: No such file or directory
```

Observation:

- The algorithm logic remains consistent across different programming languages.
- Syntax differences are the main challenge during translation.
- Python is easier to write and understand, while C requires more detailed implementation.

- Memory management is required in C but handled automatically in Python.
- Testing both versions ensures correctness of the translated code.
- Understanding the core algorithm is more important than language syntax.
